- 3. Analysis of Sr, Nd and Pb isotope ratios**
- 4. Origin of literature geochemical data**
- 5. Complementary diagrams**

1. PETROGRAPHY OF SULCIS VOLCANIC ROCKS

Petrographic observation of Sulcis volcanic rocks has revealed abundant textural variability within the volcanic sequence due to the presence of lava domes and flows and pyroclastic rocks, including the latter ignimbrite deposits with variable welding degrees.

Lava domes and flows are porphyritic (with the exception of Monte la Noce unit lava flows, which are aphyric), and consist of phenocrysts within a vitreous or partially crystallized groundmass which may present various degrees of devitrification. Enclaves may be present. Ignimbrite deposits consist of fragmentary material formed by pyroclasts, which include shards (fine vitreous fragments), pumice, crystals, and crystal fragments, and enclaves (either xenoliths or accidental lithics). Compacting and welding modified the original textures and structures of these deposits. They produced more cohesive rocks with eutaxitic texture evidenced by the elongation and flattening of shards and pumices. High welding degree and associated rheomorphism may conceal or even delete the original pyroclastic texture of an ignimbrite. Depending on their welding degree, ignimbrites appear differently affected by devitrification processes, which involve both the shards and pumices.

Regarding the mineral content there are mainly two different associations: the lower half of the volcanic succession (Andesites unit) and the rest of the sequence. Andesites present a mineral paragenesis which is dominated by plagioclase and pyroxenes. In the ignimbritic upper half of the sequence, the mineral paragenesis is dominated by feldspar (one or two), which is accompanied by opaque minerals (Fe and Ti oxides) and accessory mafic minerals. These mafic minerals are mainly pyroxenes, with presence in some units of amphibole or biotite. In comenditic units quartz may also be found. Zircon and apatite can be found as accessory minerals in some units. Vapour phase amphibole crystals, which may appear as poikilitic laths in the matrix (in comendites) or as hypidiomorphic crystals in vesicles (miarolitic texture in peralkaline or nearly peralkaline units), may be present.

Unit	Abbr.	Porphyricity	Mineral assemblage	Main characteristics
18/19	CL/PG	10	<u>sa+pl</u> +opq±zrn	Colonne/Punta Gennìo : moderately welded cineritic ignimbrite
17	PM	<1	<u>sa+ano+pl</u> +opq+m.a.±zrn	Punta Mingosa : moderately welded aphyric cineritic ignimbrite Serra di Paringianu : extremely welded and eutaxitic ignimbrite. Abundant extremely flattened light and dark grey pumices. Basal vitrophyre. Non-welded facies in northern San Pietro and Santo Antioco islands
16	SP	1-20	<u>pl+ano</u> +opq+px+amp	Paringianu : scarcely to moderately welded complex ignimbritic unit. Mostly cineritic. Low porphyricity and pumice content.
15	PA	<10	<u>sa+pl</u> +opq±bt±zrn	Carloforte : Peralkaline . Strongly welded and eutaxitic ignimbrite with abundant sanidine-bearing black pumices. Also grey and white pumices.
14	CF	10-20	<u>sa</u> +opq+ano	Monte Ulmus : Peralkaline. Strongly welded and eutaxitic aphyric ignimbrite with occasional scarce black strongly flattened pumices. Basal vitrophyre.
13	MU	<3	<u>sa+qz</u> +opq+zrn+amp(v)	Comendites : Peralkaline. Complex unit. Lava flows and variably welded ignimbrites with or without basal vitrophyre. May contain quartz phenocrysts
12	CO	5-30 up to 50	<u>sa+qz</u> +amp+opq+amp(v)	Matzaccara : variably welded ignimbritic unit. Presents bronze-coloured biotite.
11	MZ	3-20	<u>pl</u> +bt+opq	Montagna di Capo Rosso : lava flows and moderately welded lithic rich ignimbrites.
10	MCR	5-20	<u>sa+pl</u> +opq±zrn	Punta dei Cannoni : moderately to strongly welded, eutaxitic and porphyritic ignimbritic unit. Abundant big (several dm) pumices.
9	PC	up to 50	<u>ano+pl</u> +opq+cpx+opx	Nuraxi : extremely welded and eutaxitic ignimbrite. Scarce extremely flattened grey pumices. Rheomorphic structures are abundant. Basal vitrophyre.
8	NU	20-30	<u>sa+pl</u> +opq+cpx±amp(v)	Conca is Angius : slightly welded complex ignimbritic unit. Abundant pumices and accidental lithics. Degassing structures present.
7	CA	10	<u>sa+pl</u> +opq	Monte Crobu : moderately to extremely welded and eutaxitic ignimbrite. Abundant to dominant grey and occasionally black strongly flattened pumices. Rheomorphic. Basal vitrophyre.
6	MC	10-20	<u>sa+pl</u> +opq+amp(v)	Monte la Noce : lava flows, cinerites and moderately to extremely welded ignimbrites with basal vitrophyre. Aphyric.
5	MLN	<5	<u>pl</u> +opq±bt	Seruci : highly welded and eutaxitic ignimbrite with dm-sized pumices. Basal vitrophyre.
4	SE	10-20	<u>pl</u> +opq+m.a.±opx±cpx +amp(v)	Acqua sa Canna : poorly welded ignimbrite, formed by several flows deposits with pumice normal grading. Locally lithic-rich.
3	AC	10-20	<u>pl</u> +bt+opq±amp	Lenzu : strongly welded and eutaxitic ignimbrite. Abundant dm-sized pumices. Basal vitrophyre.
2	LE	10-20	<u>pl+sa</u> +opq+opx±zrn	Corona Maria : scarcely to moderately welded and eutaxitic ignimbrite. Abundant pumices and lithic fragments. Basal vitrophyre.
1	CM	10-30	<u>pl+cpx</u> +opq±bt±amp	Andesites : lava flows and domes with associated breccias
AND	AND		<u>pl+opx+cpx</u> +opq±ol	

Main petrographic characteristics of the studied units. Abbr.; unit name abbreviation. Mineral abbreviations: amp: amphibole; ano: anorthoclase; bt: biotite; cpx: clinopyroxene; ol: olivine; opq: opaque mineral; opx: orthopyroxene; pl: plagioclase; px: pyroxene; qz: quartz; sa: sanidine; zrn: zircon; a.m.: altered mafic; (v): vapour phase.

2. SELECTION OF REPRESENTATIVE WHOLE ROCK GEOCHEMICAL DATA

In the following tables major, minor and trace element compositions and CIPW norm of representative samples from Sulcis Oligo-Miocene volcanism are presented. Rock classifications follow Le Maitre *et al.* (2002); FeO and Fe₂O₃ are calculated following Middlemost (1989). Mineral abbreviations: ab: albite; acm: acmite; an: anorthite; ap: apatite; crn: corundum; di: diopside; hyp: hyperthene; ilm: ilmenite; mag: magnetite; or: orthoclase; qz: quartz; rt: rutile; ttn: titanite. <LL: below the lower limit of the calibration range; these values are given as reference but not used in discussions. na: not analysed. Minor and trace element concentrations are in µg/g (ppm). 1: XRF data; 2: XRF data, ICP data when XRF data are below the calibration range; 3: ICP data, XRF data when ICP data are not available; 4: ICP data; *: ICP value of an element for which XRF data are used. Sampling location is provided in supplementary materials in Gisbert & Gimeno (2017).

3. ANALYSIS OF Sr, Nd AND Pb ISOTOPE RATIOS

Samples for Sr and Nd isotope analysis were dissolved in HF+HNO₃, dried in HNO₃ and HCl, and brought into solution in HCl. Sr and REE were separated using DOVEX AG-50x8 (200-400 mesh) cation exchange resin, and Nd was separated using hydrogen di-ethylhexyl-phosphate (HDEHP)-coated resin. Samples for Pb isotope analysis were dissolved in HF+HNO₃, dried in HNO₃ and HCl, and brought into solution in HBr; lead separation was performed in Bio-Rad 10-ml polyethylene columns with Dowex AG1-8X anion resin, using 1N HBr to elute other elements and 6N HCl to elute Pb.

Sr and Nd isotope ratios were determined using a VG-Micromass Sector 54 TIMS with 5 Faraday cups in multi-dynamic mode. ⁸⁷Sr/⁸⁶Sr measurements were corrected for ⁸⁷Rb interferences and normalized to ⁸⁸Sr/⁸⁶Sr = 0.1194 for mass fractionation. ¹⁴³Nd/¹⁴⁴Nd measurements were corrected for ¹⁴²Ce and ¹⁴⁴Sm interferences, and normalized to ¹⁴⁶Nd/¹⁴⁴Nd = 0.7219 for mass fractionation. During the run period two isotopic reference samples (NIST SRM 987 for Sr and La Jolla for Nd) were repeatedly analysed. Unknowns were normalized to the long term average values of the laboratory, which were ⁸⁷Sr/⁸⁶Sr = 0.710248 ± 0.000050 (2σ, n=722) for NIST SRM 987 and ¹⁴³Nd/¹⁴⁴Nd = 0.511848 ± 0.000030 (2σ, n=140) for La Jolla.

Pb isotopic ratios were determined using a Thermo-Finnigan Triton TIMS. All runs were corrected for mass fractionation using international standard NIST SRM 981 and values reported by Todt *et al.* (1996). Long term relative 2σ of repeated standards measured over the 2 months period prior to the analysis are 0.04 % (²⁰⁶Pb/²⁰⁴Pb), 0.06 % (²⁰⁷Pb/²⁰⁴Pb), 0.08 % (²⁰⁸Pb/²⁰⁴Pb), 0.02 % (²⁰⁷Pb/²⁰⁶Pb) and 0.04 % (²⁰⁸Pb/²⁰⁶Pb).

Origin and available data of literature geochemical data used in this work. *Isola del Toro samples are presented in Oligo-Miocene magmatism following conclusions of this study, but in Discussion diagrams they are presented together with RPV Plio-Pleistocene lavas following prior classification. M&T: major and trace elements; EAR: European Asthenospheric Reservoir; LVC: Low Velocity Component.

5. COMPLEMENTARY DIAGRAMS

Fig. S1. Harker diagrams of major elements versus silica content, normalized to anhydrous 100 wt %. FeO* is total iron. Concentrations in wt %. White arrows indicate possible evolution trends. Symbols follow Fig. 4.

Fig. S2. Comparison between measured (grey) and age corrected (coloured) isotope ratios in studied samples ordered stratigraphically. Differences between age corrected and measured values are the largest for $^{87}\text{Sr}/^{86}\text{Sr}$. In the other isotope systems difference is not significant in terms of data interpretation. Thus, age corrected data are only used for the Sr isotope system. Symbols follow Fig. 4.

Fig. S3. Trace element multielemental diagrams (normalizing values of Sun & McDonough 1989) of the Oligo-Miocene volcanic rocks of Sardinia with $\text{MgO} > 5$ wt %. All the suites are depicted together in the bottom plot while some of the best characterized suites are depicted individually above. All the suites show similar arc-type signatures.

Sun, S.S., McDonough, W.F., 1989. Chemical and isotopic systematics of oceanic basalts; implications for mantle composition and processes, in: Saunders, A.D., Norry, M.J. (Eds.), *Magmatism in the ocean basins*. Geological Society of London, London, pp. 313-435.

Fig. S4. Th/Nb and La/Nb ratios versus SiO_2 and Mg#. Empty areas represent OM suites. Solid grey area represents PP rocks. Lack of correlation between Th/Nb and La/Nb ratios with AFC indicators (e.g. SiO_2 , Mg#) indicates that the subduction signature of most OM rocks was not introduced by crustal assimilation. In the Th/Nb vs. SiO_2 diagram, the OM suite showing correlation is the Arcuentu suite, which also shows clear crustal assimilation trends in isotope space. Symbols follow Fig. 4.

Fig. S5. Schematic diagram of the proposed hypothesis on the evolution of the subduction under Sardinia at the end of the Oligo-Miocene (OM) magmatic cycle. Orange area on the slab represents the zone of fluid release and subduction-controlled calc-alkaline magma production. Orange area on the upper plate is the zone where calc-alkaline volcanism in Sardinia occurs. Red area on the upper plate represents the extension-controlled mildly alkaline and peralkaline magmatism in Sulcis. (a) During most of the OM cycle calc-alkaline magmas erupted in western Sardinia, including the Sulcis area. (b) Towards the end of the cycle the slab began to tear northwards, parallel to the trench, south of Sardinia. (c) In Sulcis, the opening of a slab window may have reduced the input of slab fluids, thus triggering the transition from calc-alkaline to mildly alkaline magmatism as melting continued by decompression due to the existing extensional setting, and possibly also due to the thermal effect of the asthenospheric mantle upwelling through the slab window. During this stage, calc-alkaline and mildly alkaline magmas erupted contemporaneously in northern and southern Sardinia respectively.

Fig. S6 Tetrahedral diagram (Armienti & Gasperini 2007; Armienti & Longo 2011) based on Sr, Nd and Pb isotope ratios, with endmember mantle components from Hart *et al.* (1992) and Armienti & Gasperini (2007).

Fig. S7. Proposed geodynamic model of the mantle under Sardinia since the Cretaceous (not to scale). **(a)** In Cretaceous times the Central Atlantic Plume (CAP) started introducing a HIMU component into the mantle of the Euro-Mediterranean area, producing the prevalent EAR-like compositions by mixing with the pre-existing DMM mantle. In Sardinia, pre-existing asthenospheric mantle likely consisted of both EMI and DMM compositions, whereas the subcontinental lithospheric mantle presented dominant EMI component. **(b)** In Sardinia the CAP event produced an asthenospheric mantle with EMI+EAR compositions, whereas the lithospheric mantle was little affected, mostly retaining its EMI composition. **(c)** During the Oligo-Miocene, fluids released by the subducting slab favoured the flux melting of the mantle wedge and the production of calc-alkaline magmas. **(d)** At the end of the OM magmatic cycle, a slab tear opened a slab window below Sulcis, and cessation of fluids input resulted in the transition of magmatism from subduction-controlled to decompression-controlled as the mantle wedge continued to melt due to the existing extensional setting. Hot asthenospheric mantle with EAR composition ascended through the slab window, likely favouring further melting of the mantle wedge. Partial melts formed by decompression of this ascending mantle produced the Isola del Toro alkaline rocks at the very end of the OM magmatic cycle. **(e)** Extensional setting present since the late Miocene resulted in partial melting of the hotter, enriched, EAR mantle at the beginning of the Plio-Pleistocene magmatic cycle, producing the RPV in southern Sardinia. **(f)** As extension continued UPV magmas started to form below central and northern Sardinia in the subcontinental lithospheric mantle with dominant EMI compositions.
